Global Product Manager Phase Shifting Transformers der ABB

Thomas Schmidt leitet die Expertengruppe für Phasenschieber in Bad Honnef.

Das ABB Werk in Bad Honnef wurde 2000 zuständig für die Entwicklung und Vermarktung und Produktion von Phasenschiebertransformatoren innerhalb der ABB Gruppe. Herr Schmidt leitet seit dieser Zeit die Aktivitäten rund um dieses Produkt.

Thomas Schmidt war ab 1990 in verschiedenen Vertriebs- und Projektmanagement und Produktmanagement Funktionen tätig. Er hat einen Abschluss als Diplom Ingenieur der Elektrotechnik.

Control area: Generation and loads balanced

Traditionally little exchange between control areas.

Each control area balances loads with its own generation

EHV systems (220 kV and 400 kV) were used as back-up only in the European grid.

Control area: Transmission on top of generation and loads

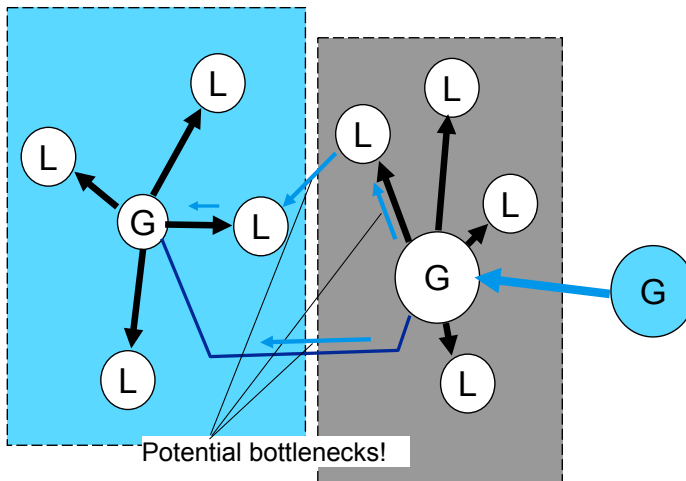

Changes in generation patterns.

New market participants.

Non-discriminating network access politically enforced.

Utilization of transmission lines differs a lot from the time they were designed. Utilization becomes quite volatile.

Bottlenecks need to be managed.

Power flow control with phase-shifting transformers
Optimization of load sharing and transmission capacity

Transmission lines with different impedances e.g. overhead / cable or 400 kV / 110 kV.

Transmission angle difference $\phi_S - \phi_L$ drives power flow with unbalanced load sharing of lines. The low impedance line is overloaded, limiting the total transmission capacity of the corridor.

PST impose an additional circulating current, thus improving the balance of power flows. The total transmission capacity increases.

Power flow control with phase shifting transformers
Smaller scale applications

- Block parasitic power flow and overload due to transmission angle differences in feeding network(s)

- Distribution of power to different systems/ customers

Pay-Back-Consideration

- Increase and control of transmission capacity, independent of the “natural” phase angle of the system, may **relieve restraints on generation**.
- **100 MW extra** for 2000 h/a allowed to the grid can generate approximately **4 MEuro/a additional revenues** (at ~ 20 Euro/MWh)
- The control of power flow is a pre-requisite for marketing transmission capacity
- **100 MW transmission capacity have a value of ~ 2 MEuro/year** (at ~ 20 Euro/kW-year)
-
- **Pay back is possible within a period of 2 - 3 years !**

Power flow control with phase-shifting transformers Phase shifting transformers are power flow controllers

$$P = \frac{V_S V_L}{X} \sin(\phi_S - \phi_L)$$

- The phase angle between two systems determines the power exchange

$$P = \frac{V_S V_L}{X + X_T} \sin(\phi_S - \phi_L + \alpha)$$

Principle of a phase shifting transformer

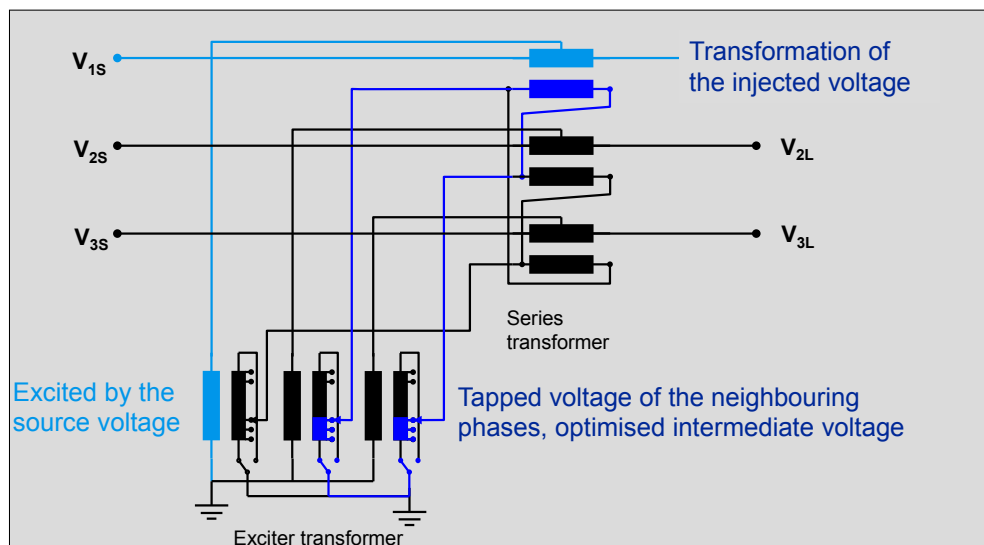

- The phase shifter rotates the phasor orientation between the source and load side.
- In pure phase shifting transformers a voltage in quadrature to the source voltage is injected into the line

Rating of a phase shifting transformer

- **Typical specification**
- Rated throughput power 300 MVA
- Rated voltages
- Angle range 10°
- Insulation levels BIL / SIL / AC
- Impedance range

- The equivalent two winding rated power (physical size) is:
 - 300 MVA x 2 sin $\Phi/2$ = 52 MVA for the main unit and
 - 300 MVA x 2 sin $\Phi/2$ = 52 MVA for the series unit

Challenges in PST design, manufacture and delivery Design

- PSTs are power transformers, with special internal connections, resulting in special loading conditions:
- Phase shift is felt as almost purely reactive loading for the magnetic circuit. Potentially strong load-dependent variations of induction in parts of the core(s).
- Regulating windings are for 100% of the transformer's rating, not just 10-20%. Dimensioning of the tap changers is critical.

**Challenges in PST design, manufacture and delivery
Current distribution**

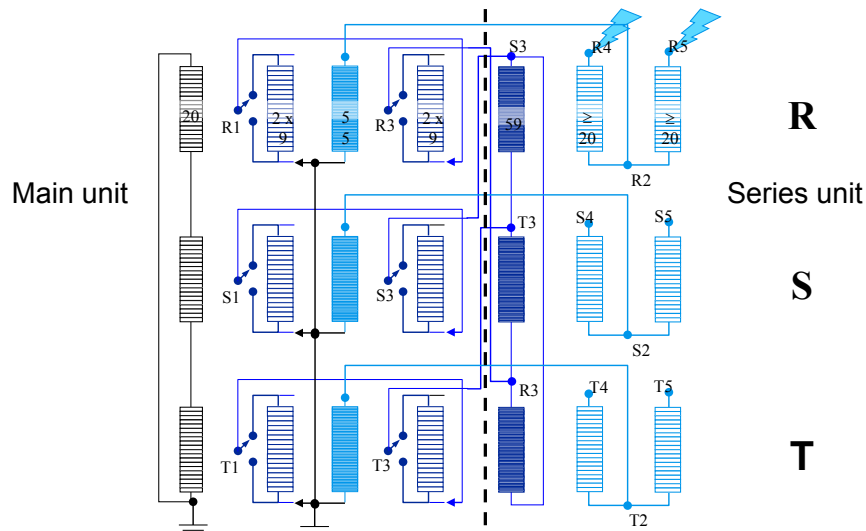

- High currents require use of large parallel conductors.
- Regulating windings with magnetic gaps expose these conductors to inhomogeneous B-field, inducing different voltages in parallel conductors
- Circulating currents may become critical.
- 2D and 3D coupled magnetic and circuit simulations.

Recent developments Switching impulse voltage distribution

- Lightning impulse 1.2/50 μs
- Necessary resolution: $\sim 0.5 \times c_{\text{light}} \times 1.2 \mu\text{s} = 180 \text{ m}$, corresponding to < 100 turns, fraction of a winding.
- Strong initial capacitive coupling, inductive coupling follows in tail of impulse.
- Time delay between winding parts causes voltage gradients.
- Switching impulse 100/1000 μs
- Necessary resolution: $\sim 0.5 \times c_{\text{light}} \times 100 \mu\text{s} = 15000 \text{ m}$, corresponding to $>$ complete winding
- Inductive and magnetic coupling dominates
- Usually only minor oscillations due to winding capacitances

Challenges

Switching impulse voltage distribution

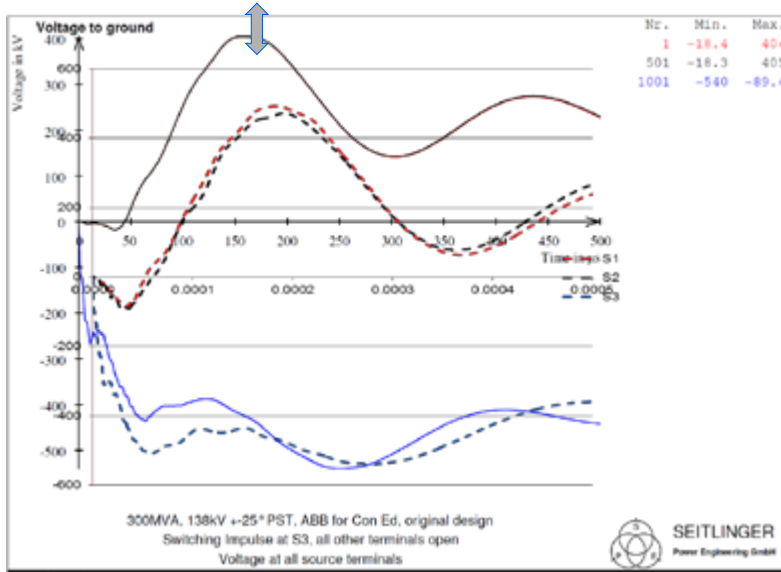

- Unexpected oscillations during switching impulse.
- Main oscillation frequency much lower than simulated, required „unphysical“ tuning of capacitances.
- Detailed measurements of internal voltage distribution available

Conclusions

- **PSTs connect entire countries**
- **The power industry still needs real hardware**
- **People rely on it every day**

- **We need to utilize modern simulation software to visualize the dielectrical as well as magnetical and thermal or mechanical behavior**
- **This allows to drive more economical solutions**
- **But we should not forget to verify in reality what we simulate**
- **We need excellent scientists and engineers who understand the limits of such simulation**
